Elementary Interval

❖ Let $I := \{ [x_i : x_i'] \mid i = 1, 2, \dots, n \}$ be n intervals on the x -axis

Sort all the endpoints into $\{ p_1, \dots, p_m \}$, $m \leq 2n$

❖ $m + 1$ elementary intervals are hence defined:

$(-\infty, p_1], (p_1, p_2], (p_2, p_3], \dots, (p_{m-1}, p_m], (p_m, +\infty)$

Discretization

👁 Within each EI, all stabbing queries share a same output

∴ If we **sort** all EI's into a vector and

store the corresponding **output** with each EI, then ...

Sorted Vector

∴ Once a query position is determined, //by an $\mathcal{O}(\log n)$ time binary search

the output can then be returned directly

// $\mathcal{O}(r)$

Worst Case

❖ Every interval spans $\Omega(n)$ EI's and a total space of $\Omega(n^2)$ is required
